Abstract: *Granulicella tundricola* hydroxynitrile lyase (*GtHNL*) catalyses the synthesis of chiral (*R*)-cyanohydrins and (*R*)- β -nitro alcohols. The triple variant *GtHNL*-A40H/V42T/Q110H (*GtHNL*-3V) was immobilised on Celite R-633 and used in monophasic MTBE saturated with 100 mM KPi buffer pH 7 for the synthesis of (*R*)-2-nitro-1-phenylethanol (NPE) in batch and continuous flow systems. Nitromethane was used as a nucleophile. A total of 82% of (*R*)-NPE and excellent enantioselectivity (>99%) were achieved in the batch system after 24 hours of reaction time. *GtHNL*-3V on Celite R-633 was successfully recycled five times. During more recycling steps a significant decrease in yield was observed while the enantioselectivity remained excellent over eight cycles. The use of a flow system enabled the continuous synthesis of (*R*)-NPE. A total of 15% formation of (*R*)-NPE was reached using a flow rate of 0.1 mL min⁻¹; unfortunately, the enzyme was not stable, and the yield decreased to 4% after 4 hours on stream. A similar yield was observed during 15 hours at a rate of 0.01 mL min⁻¹. Surprisingly the use of a continuous flow system did not facilitate the process intensification. In fact, the batch system displayed a space-time-yield (STY/mg_{enzyme}) of 0.10 g L⁻¹ h⁻¹ mg_{enzyme}⁻¹ whereas the flow system displayed 0.02 and 0.003 g L⁻¹ h⁻¹ mg_{enzyme}⁻¹ at 0.1 and 0.01 mL min⁻¹, respectively. In general, the addition of 1 M nitromethane potentially changed the polarity of the reaction mixture affecting the stability of Celite-*GtHNL*-3V. The nature of the batch system maintained the reaction conditions better than the flow system. The higher yield and productivity observed for the batch system show that it is a superior system for the synthesis of (*R*)-NPE compared with the flow approach.

Keywords: *Granulicella tundricola*; hydroxynitrile lyase; celite; immobilisation; batch; continuous flow; nitroaldol reaction; (*R*)-NPE

1. Introduction

Chiral β -nitro alcohols are compounds containing two versatile functional groups, a hydroxyl and a nitro group, attached to adjacent carbon centres of which either one or both are asymmetric. These compounds are precursors of chiral β -amino alcohols, which are important chiral building blocks for the synthesis of bioactive compounds used as pharmaceutical ingredients such as bestatin, ephedrine, norephedrine, and sphingosine [1,2]. The nitroaldol synthesis (Henry reaction) of β -nitro alcohols is base catalysed and many bases have been evaluated. Unfortunately, the unwanted side reactions such as aldol reactions, Cannizzaro disproportionation, and water elimination catalysed by these strong bases hamper their application [3]. Biocatalysis is an alternative method for producing β -nitro alcohols with high selectivity under mild reaction conditions. Six biocatalytic approaches [4–24] have been described as recently reviewed [1]. Of these, the HNL catalysed Henry reaction is particularly attractive as a new carbon-carbon bond and

a stereocentre is established simultaneously. This promiscuous HNL activity is based on the similar pK_a value of hydrogen cyanide ($pK_a = 9.21$) and nitromethane ($pK_a = 10.2$) (Scheme 1).

Scheme 1. Nitro aldol synthesis of (*R*)-2-nitro-1-phenylethanol catalysed by *GtHNL-3V*.

The synthesis of (*R*)-2-nitro-1-phenylethanol catalysed by *GtHNL-3V*, a more active and stable variant compared with the wild-type enzyme, was reported using a biphasic system in a batch process [12]. Long reaction times (24 h) were needed to achieve 72.8% of conversion and 94.5% of enantiomeric excess. Flow chemistry is an important tool for process intensification and has been reported to reduce reaction times concomitantly improving enantioselectivities by suppressing undesired side reactions. Additionally, it enhances safety and among others reduces reaction volumes [25–32]. At the same time, it requires the enzymes to be immobilised, which often improves enzyme stability. Celite is an environmentally friendly, food grade carrier that has been used for the immobilisation of several HNLs with good results [33–35]. This cheap hydrophilic carrier has the ability to bind water efficiently. This enables a local aqueous environment around the enzyme and avoids the use of chemicals during the enzyme immobilisation which might affect the enzyme stability [36]. Indeed, the successful immobilisation of *GtHNL-3V* on Celite R-633 for the synthesis of (*R*)-mandelonitrile in batch and flow systems has been reported [37]. Good conversion, excellent enantioselectivity, and high stability were achieved in both systems. In addition, the continuous flow system enabled an important increase in the space-time-yield (65 times) compared with the batch system.

Herein, we aim to evaluate the *GtHNL-3V* catalysed nitroaldol reaction for the synthesis of (*R*)-2-nitro-1-phenylethanol in batch and flow systems. For this, *GtHNL-3V* was immobilised on Celite R-633. Monophasic MTBE saturated with 100 mM KPi buffer pH 7 was employed as reaction medium. The activity, stability and productivity of batch and flow systems were investigated.

2. Results and Discussion

GtHNL-3V was successfully overexpressed in *E. coli* BL21(DE3) and purified by a heat treatment. It displayed a specific activity of 2.2 ± 0.05 U mg^{-1} for the cleavage of *rac*-mandelonitrile into benzaldehyde and hydrogen cyanide. The enzyme was immobilised on Celite R-633 by adsorption of an enzyme solution in 100 mM potassium phosphate buffer pH 7 as described earlier [37]. The synthesis of (*R*)-NPE (Scheme 1) was performed with MTBE saturated with the same buffer both for batch and flow systems.

2.1. Batch Reactions

The initial experiments were directed towards rigorously establishing a system that enabled recycling experiments. The immobilisation of *GtHNL-3V* on Celite R-633 was therefore evaluated by a leaching test under reaction conditions. The immobilised enzyme was removed from the reaction mixture after 2 hours and samples were taken shortly after removing the enzyme and after 4 hours. If the enzyme does not leach from the carrier, no further conversion is expected. Indeed, this was the case. *GtHNL-3V* did not leach from Celite R-633 into the reaction medium (Figure S1). Different hydroxynitrile lyases (HNLs) such as *Prunus amygdalus* HNL (*PaHNL*) [35], *Manihot esculenta* HNL [34], *Arabidopsis thaliana* HNL (*AtHNL*) [33] and *GtHNL* [37] have been immobilised on Celite for the synthesis of cyanohydrins using buffer saturated organic solvents as reaction medium. In

all cases, the enzyme did not leach from Celite. The insolubility of the enzyme in organic solvents explains these results.

Having established that *GtHNL-3V* does not leach from Celite R-633 under reaction conditions, time studies with different enzyme loadings of immobilised *GtHNL-3V* were performed (Figure 1). A total of 75% formation of (*R*)-NPE and excellent enantioselectivity (>99%) were achieved with 22 U of *GtHNL-3V* (5.74 mg) on 50 mg Celite R-633 after 4 hours. Commonly a low pH is used for the HNL catalysed synthesis of cyanohydrins to avoid the chemical racemic background reaction. This non-selective product formation is not relevant for the nitroaldol reaction, most probably due to the reduced solubility of nitromethane in the aqueous phase [9,15]. Therefore, 100 mM potassium phosphate buffer pH 7 was used for the saturation of MTBE. This enables higher *GtHNL-3V* activity as it is in the ideal pH range of the enzyme. Neither Celite R-633 nor 0.25 mM MnCl₂ (negative controls) catalysed the non-selective nitroaldol reaction in the absence of *GtHNL-3V* (data not shown). An earlier report [12] showed 30% formation of (*R*)-NPE and enantioselectivity of 95.8% after equal reaction time using 0.5 mg of *GtHNL-3V*, however, in a biphasic system. The *Hevea brasiliensis* HNL (*HbHNL*) catalysed synthesis of several chiral β-nitro alcohols in a biphasic system [9] provided 63% of (*S*)-NPE with 92% *ee*. In kinetic resolutions, another approach commonly used to synthesise chiral β-nitro alcohols with HNLs, the (*S*)-selective HNL from *Hevea brasiliensis* (*HbHNL*) catalysed the decomposition of (*S*)-NPE yielding (*R*)-NPE [13]. The resolution was conducted to almost completion (49%) with excellent enantioselectivity (95%). Product inhibition due to the aldehyde formed during the reaction was overcome by adding hydrogen cyanide to the reaction mixture, this enabled the formation of the less inhibitive mandelonitrile. Likewise, the *AtHNL* catalysed kinetic resolution of *racemic* NPE has been reported [15]. *AtHNL* (27 U) immobilised on Celite R-545 was used in a biphasic system which resulted in 47% of conversion and 97% of enantiomeric excess after six hours of reaction time. Overall, the good yield and excellent enantioselectivity achieved by *GtHNL-3V* on Celite using buffer saturated MTBE as a reaction medium surpasses the reduced *ee*, mass transfer, and work-up limitations of the biphasic approach as well as the limited yield (50%) of kinetic resolutions.

In the cyanohydrin synthesis reactions, the Celite immobilised HNLs all had to be dried before their application in buffer saturated solvents. Here the opposite was observed. *GtHNL-3V* on Celite R-633 was not dried after immobilisation. When dried after immobilisation, the synthesis of (*R*)-NPE dropped to 41.12 ± 0.62% even after prolonged reaction times (24 h). The water content and more accurately the water activity (*a_w*) of Celite-*GtHNL-3V* is a crucial parameter in biocatalysis since enzymes, excluding lipases [38], need some water for conformational flexibility. Earlier studies [33] have shown the influence of the water content on the activity of immobilised *AtHNL* on Celite R-633, where 10% (*w/w*) water content inside *AtHNL*-Celite was needed for optimal enzymatic activity. Similarly, the stability of *MeHNL* as CLEA or immobilised on Celite R-633 is highly dependent on the water content entrapped in the carrier [34]. In general, the use of buffer saturated organic solvent provides the water that enzymes need for flexibility and to facilitate reproducibility. However, in this reaction a high concentration of nitromethane was used. This compound has a low log *P* of −0.24 [39] and influences the overall polarity of the reaction mixture. While buffer saturated MTBE would normally represent an *a_w* of 1, this is no longer the case at high nitromethane concentrations. Thus, the water entrapped in Celite-*GtHNL-3V* can diffuse into the reaction mixture, as a result, the enzyme was deactivated rapidly. Earlier, the effect of *a_w* on enzymes in organic media was reported [40]. The activity and enantioselectivity of *MeHNL*-CLEA in organic solvents with different polarity at different *a_w* has been investigated previously. The release of water from *MeHNL*-CLEA (and subsequent deactivation) depended on changes in the polarity of the solvent due to the addition of reagents. The negative effect of dehydration on the catalytic activity of enzymes has been extensively studied [41–43].

Figure 1. Synthesis of (*R*)-2-nitro-1-phenylethanol using different enzyme loadings on 50 mg of Celite R-633. Solid line (22 U, final *ee* > 99%), dashed line (10 U, final *ee* > 99%) and dotted line (1 U, final *ee* > 99%). Conditions: Ratio benzaldehyde:nitromethane, 1:50, 20 mM benzaldehyde in MTBE saturated with 100 mM KPi buffer pH 7, 1 M nitromethane, 20 mM 1,3,5-tri-isopropylbenzene in MTBE saturated with 100 mM KPi buffer pH 7 as internal standard (I.S) and *GtHNL*-3V immobilised on 50 mg Celite R-633. The immobilised *GtHNL*-3V was freely placed into the glass reaction vial. Reaction volume 1 mL. The reaction was shaken at 1200 rpm at 30 °C. Error bars correspond to the standard deviation of duplicates (*n* = 2). The yield of (*R*)-NPE was calculated by the ratio of (*R*)-NPE concentration to the initial benzaldehyde concentration.

Omitting the drying step after the enzyme immobilisation enabled high catalytic activity and excellent enantioselectivity. The stability of *GtHNL*-3V on Celite R-633 for the synthesis of (*R*)-NPE in the batch system was evaluated by a recycling study (Figure 2). An enzyme loading of 10 U/50 mg Celite was used to observe any loss of activity due to enzyme deactivation. Higher activity and stability were observed when Celite-*GtHNL*-3V was rehydrated with 50 μ L of 100 mM potassium phosphate buffer pH 7 after each cycle (Figure 2, blue bars). The increasing yield during the first three cycles might be related to the addition of a buffer after each cycle and suggests that the a_w was not optimal for the enzymatic activity during the first two cycles. After five cycles a significant decrease in activity was observed. In contrast, the experiments without buffer addition between cycles displayed lower yields and lower recyclability (Figure 2, dashed bars). Remarkably, an excellent enantiomeric excess was achieved under all conditions evaluated. The recyclability of *GtHNL*-3V immobilised on Celite R-633 for the synthesis of (*R*)-mandelonitrile has been reported for the cyanohydrin synthesis [37]. A high stability of the enzyme was observed. The biocatalyst was recycled eight times with excellent enantioselectivity whereas yields gradually dropped to >70% over all cycles. Recently, the stability of *AtHNL* on Celite R-545 for the kinetic resolution of *racemic* NPE was reported [15]. The immobilised enzyme was stable during four cycles but a decrease in enantioselectivity (from 97% to 40%) was reported. According to the authors, enzyme leaching might be a possible explanation since the reaction was performed in a biphasic system and the immobilisation of *AtHNL* on Celite R-545 involves weak interactions such as hydrogen

bonding and van der Waals forces. The use of a buffer saturated organic solvent as a reaction medium is a straightforward approach to circumvent this limitation.

Figure 2. Recycling of *GtHNL-3V* on Celite R-633 (10 U/50 mg) for the synthesis of (*R*)-2-nitro-1-phenylethanol in eight successive cycles. Blue bars (yields with the addition of 50 μ L of 100 mM potassium phosphate buffer pH 7 starting after the first cycle), dashed bars (yields without addition of 100 mM potassium phosphate buffer pH 7 between cycles), enantiomeric excess (dotted line and diamonds). Conditions: Ratio benzaldehyde:nitromethane, 1:50, 20 mM benzaldehyde in MTBE saturated with 100 mM KPi buffer pH 7, 1 M nitromethane, 20 mM 1,3,5-tri-isopropylbenzene in MTBE saturated with 100 mM KPi buffer pH 7 as internal standard (I.S) and *GtHNL-3V* immobilised on 50 mg Celite R-633. The immobilised *GtHNL-3V* was freely placed into the glass reaction vial. Reaction volume 1 mL. The reaction was shaken at 1200 rpm at 30 $^{\circ}$ C. Error bars correspond to the standard deviation of duplicates ($n = 2$). The enzyme was washed for 1 minute (twice) with MTBE saturated with 100 mM KPi buffer pH 7 after each cycle. Reaction time: 2 hours. Error bars correspond to the standard deviation of duplicates ($n = 2$). The yield of (*R*)-NPE was calculated by the ratio of (*R*)-NPE concentration to the initial benzaldehyde concentration.

2.2. Continuous Flow Reactions

The immobilisation of *GtHNL-3V* allows the continuous synthesis of (*R*)-NPE leading potentially to process intensification. The enzyme was tested in flow either re-hydrated or not dried after immobilisation with a flow rate of 0.1 mL min⁻¹ or 0.01 mL min⁻¹, respectively (Figure 3). Figure 3A shows that the enzyme is not stable at 0.1 mL min⁻¹ and a steady decrease in yield was observed over time during 4 hours on a stream. The use of a lower flow rate (0.01 mL min⁻¹) (Figure 3B) allowed the continuous synthesis of (*R*)-NPE over a period of 15 hours. The potentially enhanced stability at a lower flow rate might be explained by the improved ability of Celite to keep the water entrapped whereas higher flow rate removes the water inside Celite-*GtHNL-3V* more rapidly. This suggests that a higher yield might be possible at longer residence times. Indeed, when *GtHNL-3V* on Celite R-633 and substrates were allowed to react during 2 h or even 20 h in the flow reactor the yield increased to 47.5% and 80.3%, respectively (Table 1). This pulsed flow approach can solve the problem of water removal.

Likewise, the development of a biphasic system is another approach to maintain Celite-*GtHNL-3V* hydration over time. Figure 3C shows a higher yield of (*R*)-NPE (44%) during the first 30 minutes of reaction time. Unfortunately, the biphasic system (50/50%) was not stable and a significant decrease in yield was observed after 1 hour. This can be explained by the leaching of the enzyme to the reaction medium due to the weak interactions between Celite-*GtHNL-3V* and the solubility of the enzyme in the reaction medium

as observed earlier for a similar system [15]. The immobilization of *GtHNL-3V* by covalent attachment might be a viable alternative to overcome the leaching limitation observed in this biphasic system. Remarkably, the enantiomeric excess is excellent in all conditions evaluated.

Figure 3. Stability of *GtHNL-3V* on Celite R-633 for the continuous synthesis of (*R*)-2-nitro-1-phenylethanol in a packed bed reactor. (A) Conditions: Ratio benzaldehyde:nitromethane, 1:50, 20 mM benzaldehyde, 1 M nitromethane, 20 mM 1,3,5-tri-isopropylbenzene as internal standard (I.S) in MTBE saturated with 100 mM KPi buffer pH 7 with *GtHNL-3V* (400 U) immobilised on 300 mg Celite R-633. The flow rate was 0.1 mL min⁻¹. The enzyme was dried 24 h under vacuum in a desiccator over silica gel and re-hydrated with 1 mL 100 mM potassium phosphate buffer pH 7 prior to the reaction. (B) Conditions: Ratio benzaldehyde:nitromethane, 1:50, 20 mM benzaldehyde, 1 M nitromethane, 20 mM 1,3,5-tri-isopropylbenzene as internal standard (I.S) in MTBE saturated with 100 mM KPi buffer pH 7 with *GtHNL-3V* (450 U) immobilised on 500 mg Celite R-633. The flow rate was 0.01 mL min⁻¹. The enzyme was not dried after its immobilisation. (C): Conditions: Ratio benzaldehyde:nitromethane, 1:50, 40 mM benzaldehyde, 2 M nitromethane, 40 mM 1,3,5-tri-isopropylbenzene as internal standard (I.S) in MTBE saturated with 100 mM KPi buffer pH 7, 100 mM KPi buffer pH 7 with *GtHNL-3V* (450 U) immobilised on 500 mg Celite R-633. The reaction was performed in a biphasic 50/50% system. The flow rate was 0.1 mL min⁻¹. The enzyme was not dried after its immobilisation. Yield (bars) and enantiomeric excess (dashed lines). Error bars correspond to the standard deviation of duplicates ($n = 2$). The yield of (*R*)-NPE was calculated by the ratio of (*R*)-NPE concentration to the initial benzaldehyde concentration.

Table 1. Influence of residence time on the continuous synthesis of (*R*)-NPE catalysed by *GtHNL-3V* on Celite R-633 in potassium phosphate buffer (100 mM, pH 7) saturated MTBE as reaction medium.

Flow Rate (mL min ⁻¹)	Residence Time ^a (min)	Enzyme Loading (U)	Yield (<i>R</i>)-NPE ^b (%)	ee (%)
0.1	7.3	400	15.7 ^c	>99
0.01	43.8	450	16.2 ^d	>99
0.01	120 ^e	450	47.5	>99
0.01	1200 ^e	450	80.3	>99

^a Calculated as the ratio of reaction volume to flow rate. The reaction volume was calculated based on the pore volume of Celite R-633 (1.46 mL g⁻¹ [44]) and the amount (g) of carrier used. ^b Calculated by the ratio of (*R*)-NPE concentration to the initial benzaldehyde concentration. ^c Calculated after 30 min reaction time. ^d Average of 15 hours of reaction time. ^e The pump was turned off to allow the desired retention time.

2.3. Comparison between Batch and Continuous Flow Systems

A fair comparison between batch and continuous flow systems can be made based on their space-time-yields (STYs). The product formation over time is not a linear function in batch and flow systems; thus, the comparison must be made at the same level of conversion [25]. Table 2 shows the STYs of the batch and continuous flow systems using

MTBE saturated with 100 mM KPi buffer pH 7 as reaction medium. The batch and flow systems displayed similar productivity at 0.01 mL min⁻¹. The use of a higher flow rate (0.1 mL min⁻¹) improved the STY (g L⁻¹ h⁻¹) seven times. However, the enzyme was not stable at this flow rate (Figure 3A). When the amount of enzyme used for the reactions is taken into account, the productivity of the batch system is 5 and 37 times higher compared with both flow rates (0.1 mL min⁻¹ and 0.01 mL min⁻¹) respectively. The reaction conditions for the Celite-*GtHNL*-3V catalysed synthesis of (*R*)-NPE evaluated in this study were more stable and controlled in the batch system. This explains its higher productivity. This result is unexpected since flow systems commonly allowed process intensification [25,26,37,45,46]. However, the high concentration (1 M) and low polarity (log *P* = -0.27) of nitromethane might not maintain a constant *a_w* on Celite-*GtHNL*-3V. While significant fluctuations in enzyme activity and therefore yield were observed, remarkably the enantioselectivity of the reaction was unaffected and always excellent.

Table 2. Comparison of batch and flow systems based on their productivity.

	Batch	Flow
STY ^a (g L ⁻¹ h ⁻¹)	0.60	4.31 ^b 0.69 ^c
STY ^a (g L ⁻¹ h ⁻¹ mg _{enzyme} ⁻¹)	0.10	0.02 ^b 0.003 ^c

^a Calculated at similar yield levels (*circa* 16%) ^b Calculated at 0.1 mL min⁻¹. ^c Calculated at 0.01 mL min⁻¹.

3. Materials and Methods

3.1. Chemicals

Except when reported otherwise, all chemicals were obtained from Sigma Aldrich (Schnelldorf, Germany). Isopropanol and heptane were of HPLC graded (≥99%) and used as HPLC solvents. The 1,3,5-triisopropylbenzene (97%) was from Fluka Chemie (Buchs, Switzerland). (±)-Mandelonitrile from Across Organics (Geel, Belgium) was purified by flash chromatography (PE/MTBE 9:1/3:7). The (±)-2-nitro-1-phenylethanol was prepared according to the literature [47].

3.2. Cloning and Heterologous Expression of *Granulicella tundricola* HNL (*GtHNL*)

The pUC57 shuttle vector containing the gene encoding *GtHNL*-A40H/V42T/Q110H, codon optimised for *E. coli* was obtained from Bio Basic INC (Markham, Canada) and used to transform *E. coli* Top 10. The gene encoding *GtHNL*-A40H/V42T/Q110H gene was cloned into the pET28a expression vector using *Nco*I and *Hind*III restriction enzymes. The resulting pET28a-*GtHNL*-A40H/V42T/Q110H expression vector was cloned into *E. coli* TOP 10 to obtain a stable host for plasmid DNA and sequenced to ensure the successful introduction of the H96A mutation (Table S1). Finally, pET28a-*GtHNL*-A40H/V42T/Q110H was used to transform the expression host *E. coli* BL21(DE3). The enzyme cultivation was performed in accordance with the literature [37]. A preculture was prepared by inoculating one single colony of *E. coli* BL21(DE3)-pET28a-*GtHNL* in 10 mL of LB medium with kanamycin (40 µg/mL) and incubated overnight (New Brunswick Scientific Incubator Shaker Excella E24 Series, Nijmegen, The Netherlands) at 37 °C, 180 rpm. Then, this preculture was used for the inoculation of 1 L of LB medium containing kanamycin (40 µg/mL) and incubated at 37 °C, 120 rpm. When the OD₆₀₀ reached 0.7–0.9 the gene expression was induced by adding 1 mL of 0.1 M isopropyl β-D-thioacetamide (IPTG) per litre of culture (0.1 mM IPTG final concentration) and cultivation was continued overnight at 25 °C, 120 rpm. Moreover, 100 µL of 1 M MnCl₂ was added per litre of culture at the induction time (0.1 mM Mn²⁺ final concentration). Cells were harvested at 4

°C, 5000 rpm during 20 min (Sorvall RC6, Thermo Scientific, Landsmeer, The Netherlands). The supernatant was discarded, and the pellet was washed with 20 mL of 10 mM sodium phosphate buffer, pH 7, and stored at −80 °C.

3.3. Enzyme Purification

The pellets of *GtHNL-3V* were resuspended in lysis buffer (50 mM potassium phosphate buffer + DNase) pH 7 and lysed in a cell disruptor (Constant Systems Ltd., Daventry, United Kingdom) at 20 kPSI and 4 °C to avoid protein denaturation. The cell free extract (CFE) was collected as the supernatant after centrifugation at 4500 g, 1 h, 4 °C, heated during 30 min at 65 °C, and centrifuged during 15 min at 4500 g. The purified enzyme was found as the supernatant.

3.4. Enzymatic Activity Assay

GtHNL-3V activity was measured spectrophotometrically (Agilent Technologies Cary 60 UV-VIS, Amstelveen, The Netherlands) using a method previously reported [48]. The cleavage of *rac*-mandelonitrile into benzaldehyde and hydrogen cyanide was followed at 280 nm and 25 °C in quartz glass cuvettes. To 1300 µL of reaction buffer (100 mM sodium oxalate buffer, pH 5), 200 µL of enzyme solution (diluted in reaction buffer) and 500 µL of 60 mM *rac*-mandelonitrile solution (dissolved in 3 mM oxalic acid, pH 3) were added. The background reaction was evaluated without enzyme and its slope was subtracted in the final calculation. The activity was calculated based on the following equation:

$$\text{Activity} = (2.0 \times \Delta A/\text{min}) / (\epsilon_{280} \times 1 \times 0.2) \text{ [U/mL diluted sample]}$$

where

$$\begin{aligned} \Delta A/\text{min} &= \Delta A/\text{min}_{\text{sample}} - \Delta A/\text{min}_{\text{blank}} \\ \epsilon_{280} &= 1.376 \text{ [mM}^{-1} \times \text{cm}^{-1}] \end{aligned}$$

One unit of HNL activity is defined as one micromole of *rac*-mandelonitrile converted per minute in 100 mM sodium oxalate buffer pH 5 at 25 °C.

3.5. Immobilisation of *GtHNL* on Celite R-633 by Adsorption

Enzyme immobilisation on Celite R-633 was performed according to the literature [34,37] with slight modifications. Celite R-633 has a pore diameter of 6.5 µm, a pore volume of 1.47 mL g^{−1} and a water absorption capability of 240% (Supplementary Information S2). It was washed with 100 mM potassium phosphate buffer pH 7 using a Büchner funnel and dried 24 h under vacuum in a desiccator over silica gel or used directly. Given volumes of *GtHNL-3V* were concentrated with Amicon ultrafiltration filters with a 10 kDa MW cut-off, and subsequently added dropwise to Celite R-633 and dried 24 h under vacuum in a desiccator over silica gel. The ratio of enzyme solution to carrier (µL:mg) was 2:1. The enzyme concentration in the solutions was adjusted to the required amount of enzyme for the immobilisation. By using this ratio of enzyme solution to Celite, the enzyme solution was completely absorbed by the carrier, ensuring that all the enzyme was immobilised into the porous material. The immobilised enzyme was stored in the fridge at 4 °C when needed.

3.6. Synthesis of (*R*)-2-nitro-1-phenylethanol in the Batch System

Several (*R*)-2-nitro-1-phenylethanol synthesis were performed with 50 mg of immobilised *GtHNL-3V* on Celite R-633. The reaction conditions were as follows: 20 mM benzaldehyde, 20 mM 1,3,5-tri-isopropylbenzene (internal standard), 1 M nitromethane and MTBE saturated with 100 mM KPi buffer pH 7, 50 mg immobilised enzyme, 1200 rpm, and 30 °C. Shaking and temperature were controlled by using an Eppendorf thermomixer (Hamburg, Germany). The saturated MTBE was prepared by adding 5 mL of 100 mM KPi buffer pH 7 to 25 mL of dry MTBE. Reaction volume: 1 mL. The ratio benzaldehyde to

nitromethane was 1:50. The immobilised *GtHNL-3V* was freely placed into the glass reaction vial.

3.7. Enzyme Recyclability in the Batch System

The enzyme recyclability was determined through several cycles of (*R*)-2-nitro-1-phenylethanol synthesis according to the literature [34,37]. Between each cycle the immobilised enzyme was washed twice for 1 minute with MTBE saturated with 100 mM KPi buffer pH 7. When required, 50 μ L of 100 mM KPi buffer were added to the immobilised enzyme. At the end of the working day the immobilised enzyme was stored at 4 °C in fresh MTBE saturated with 100 mM KPi buffer pH 7. The immobilised *GtHNL-3V* was freely placed into the glass reaction vial. The saturated MTBE was prepared by adding 5 mL of 100 mM KPi buffer pH 7 to 25 mL of dry MTBE

3.8. Enzyme Stability in Continuous Flow in a Monophasic KPi Saturated MTBE System

A 1 mL stainless steel flow reactor was used for the continuous synthesis of (*R*)-2-nitro-1-phenylethanol. Ten centimetre of polytetrafluoroethylene (PTFE) tubing with 1.5 mm inner diameter connected a syringe pump (Knauer, Berlin, Germany) with the reactor. The stability of 400 U of immobilised *GtHNL-3V* on 300 mg Celite R-633 was evaluated by performing a synthesis reaction during 4 hours at 0.1 mL min⁻¹ (reaction volume = 0.73 mL). Likewise, the stability of 450 U of immobilised *GtHNL-3V* on 500 mg Celite R-633 was evaluated during 15 hours at 0.01 mL min⁻¹ (reaction volume = 0.44 mL). The ratio was benzaldehyde:nitromethane, 1:50, 20 mM benzaldehyde, 1 M nitromethane, 20 mM 1,3,5-tri-isopropylbenzene as internal standard (I.S) in MTBE saturated with 100 mM KPi buffer pH 7. The reactions were performed at room temperature. The saturated MTBE was prepared by adding 5 mL of 100 mM KPi buffer pH 7 to 25 mL of dry MTBE. Samples were drawn at regular intervals and analysed by chiral HPLC. The flow rate was checked at each sampling time by the difference of weight.

3.9. Enzyme Stability in Continuous Flow in a Biphasic System

A similar setup as described in 3.8 was used. In this case, two syringes were connected to a mixing unit (T-piece assembly) to ensure a mixture of substrates and buffer. Syringe 1 was used for 40 mM benzaldehyde, 2 M nitromethane, and 40 mM in 1,3,5-tri-isopropylbenzene in MTBE saturated with 100 mM KPi pH 7. Syringe 2 was used for 100 mM KPi pH 7. The stability of 450 U of immobilised *GtHNL-3V* on 500 mg Celite R-633 was evaluated by performing a synthesis reaction during 3 hours at 0.1 mL min⁻¹ (reaction volume = 0.73 mL). The reaction was performed in a biphasic 50/50% system. The enzyme was not dried after its immobilisation. The reactions were performed at room temperature. Saturated MTBE was prepared by adding 5 mL of 100 mM KPi buffer pH 7 to 25 mL of dry MTBE. Samples were drawn at regular intervals and analysed by chiral HPLC. The flow rate was checked at each sampling time by the difference of weight.

3.10. Analysis

Samples (50 μ L) were taken at different times during the reaction run and added to 450 μ L of heptane:2-propanol 90:10 in 1.5 mL Eppendorf tubes. A small amount of anhydrous magnesium sulphate (MgSO₄) was used to remove the water from the solution and the Eppendorf tubes were centrifuged at 13,000 rpm for 1 min. The supernatant was transferred to a 1.5 mL HPLC vial and 10 μ L was injected into the HPLC (Chiralcel OD column, column size: 0.46 cm I.D \times 25 cm)(Munich, Germany). Heptane and 2-propanol were used as mobile phase with a flow rate of 1 mL/min and the UV detector was set at 210 nm. The column temperature was set at 40 °C. The samples in the autosampler were maintained at 4 °C.

Supplementary Materials: The following are available online at www.mdpi.com/article/10.3390/catal12020161/s1, Figure S1: Leaching assay for *GtHNL* on Celite R-633 (10 U/50 mg Celite R-633), Table S1: *GtHNL*-A40H/V42T/Q110H gene sequence and the company information sheet on Celite as Supplementary Information S2.

Author Contributions: U.H. conceptualized and supervised the study; J.C., L.T. and M.A. performed the experiments; P.-L.H. reviewed the manuscript and supervised the study. J.C. wrote and edited the manuscript. All authors have read and agreed to the published version of the manuscript.

Funding: This research was funded by the Secretary of Higher Education, Science, Technology and Innovation of Ecuador (Senescyt) and Universidad Laica Eloy Alfaro de Manabí (ULEAM).

Data Availability Statement: The data presented in this study are available on request from the corresponding author.

Acknowledgments: The authors thank Eman Abdelraheem for the synthesis of (\pm)-2-nitro-1-phenylethanol.

Conflicts of Interest: The authors declare no conflict of interest. The funders had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript, or in the decision to publish the results.
